The **aim of the present study** was to obtain and characterize (structural and functional) of nanostructured membranes with fibrillar consistency obtained using electrospinning technique with applications in tissue engineering (TE).

The first section of this thesis provides a **literature background**, describing concepts referring to **nanomaterials** and **nanofibrous materials for TE (bone tissue engineering and wound dressing applications)**, as well as electrospinning method, from basic concepts to challenges in electrospinning and nanofibrous scaffolds for tissue regeneration.

First, the thesis introduces the synthesis and evaluation of silica (SiO_2) nanofibrous mats produced through electrospinning and subsequent calcination with tetraethyl orthosilicate (TEOS) and polyvinyl alcohol (PVA). This is the first report on the development of fibrous silica architectures, using tetraethyl orthosilicate (TEOS) and polyvinyl alcohol (PVA) during the self-assembly electrospinning (ES) processing (a layer of flat fibers must first be created in self-assembly electrospinning before fiber stacks can develop on the fiber mat). The elemental and microstructural details of the produced scaffolds were assessed through a combination of infrared and thermal analyses, as well as advanced microscopic techniques. The study of the development of pure silica networks was made following a calcination process at a temperature of 500°C for a duration of 2 hours. These networks were found to be composed of nanofibers that were uniformly distributed and randomly orientated, exhibiting smooth surfaces. Subsequently, the samples underwent evaluation to determine their suitability for application in bone tissue engineering, employing a murine animal model. Calcined silica fibrous scaffolds (SiO_2 _0h aging and SiO_2 _1.5h aging) shown enhanced outcomes in mineralization and the generation of new bone. Additionally, the incorporation of vitronectin into calcined networks resulted in enhanced mineralization and facilitated the production of new bone through the promotion of cell adhesion to the fibers. The findings confirmed the suitability of electrospun silica nanofibers as effective options for scaffolding in bone tissue engineering applications.

Injuries and diseases of the skin require accurate treatment using nontoxic and noninvasive biomaterials, which aim to mimic the natural structures of the body. There is a strong need to develop biodevices capable of accommodating nutrients and bioactive molecules and generating the process of vascularization. Electrospinning is a robust technique, as it can form fibrous structures for tissue engineering and wound dressings. The best way of forming such meshes for wound healing is to choose two polymers that complement each other regarding their properties.

Second, the present doctoral thesis focuses on the manufacture and characterisation of an electrospun nanofiber mesh composed of polyvinyl alcohol, chitosan, and usnic acid. On the one hand, PVA is a water-soluble synthetic polymer widely used for the preparation of hydrogels in the field of biomedicine owing to its biocompatibility, water solubility, nontoxicity, and considerable mechanical properties. PVA is easy to subject to electrospinning and can offer strong mechanical stability of the mesh, but it is necessary to improve its biological properties. On the other hand, CS has good biological properties, including biodegradability, nontoxicity, biocompatibility, and antimicrobial properties. Still, it is harder to electrospin and does not possess as good mechanical properties as PVA. As these structures also allow the incorporation of bioactive agents due to their high surface area-to-volume ratio, the interesting point was to incorporate usnic acid into the structure as it is a natural and suitable alternative agent for burn wounds treatment which avoids an improper or overuse of antibiotics and other invasive biomolecules. The primary objective of this study is to investigate the potential applications of this nanofiber mesh in the field of wound healing. The physicochemical analysis demonstrated the presence of a fibrous morphology, with the fibers exhibiting diameters ranging from 14.86 nm to 75.06 nm. Notably, the majority of the fibers fell between the size range of 30 to 40 nm. The scanning electron microscopy (SEM) pictures revealed that the nonwoven assembly exhibited a linear morphology characterized by a random orientation. The SEM images revealed fibers with ramifications that exhibited a significantly porous structure, making them appropriate for utilization in wound healing due to their ability to mimic the natural extracellular matrix (ECM). The XTT assay demonstrated significant findings at both the 48-hour and 72-hour time points for the 5%PVA_2%CS-UA sample. Specifically, it exhibited a notable increase in cell viability, approximately 30% higher than that of the control group. The confirmation of this fact establishes the biocompatibility of the electrospun mesh with usnic acid, indicating its potential as a viable biodevice capable of supporting cellular proliferation and growth. The cell viability seen using fluorescence microscopy was found to be similar to that of the control group, indicating that the nanofiber meshes did not demonstrate any cytotoxic properties. The 5%PVA_2%CS-UA formulation exhibited enhanced anti-biofilm efficacy against the *S. aureus* strain, as observed from the perspective of biofilm growth. In brief, the results mentioned above significantly support the potential of applying electrospun nanofiber meshes composed of polyvinyl alcohol (PVA), chitosan, and usnic acid as a viable material for the purpose of wound healing.

The third objective of this study was to develop and characterize nanostructured membranes with fibrillar consistency based on recycled PET and magnetite nanoparticles functionalized with usnic acid by electrospinning technique. The obtained PET nanostructured membranes exhibited enhanced antibacterial and antibiofilm properties against both Gram-positive (*S. aureus*) and Gram-negative (*P. aeruginosa*) bacterial strains, as well as opportunistic yeast *C. albicans*. The samples obtained at higher feed rates exhibited superior antibacterial potential, which can be attributed to the development of denser meshes and a higher concentration of magnetite nanoparticles on their surface (as observed qualitatively). Furthermore, it was shown that the fibrillar mats nanoparticle-containing exhibited minimal toxicity when tested in both in vitro and in vivo conditions. The findings present novel possibilities for PET recycling, including its integration with diverse antimicrobial inorganic nanostructures to produce enhanced fibrillar materials with antimicrobial and antibiofilm characteristics. These developments have the potential for expanded utilization within the food industry, particularly in the context of food packaging applications. Additionally, their application in the biomedical field could be promising for the development of antimicrobial medical textiles.

A variety of materials has been developed by the utilization of the electrospinning process. The electrospinning technique is characterized by a high level of complexity, with the final result being influenced by a wide range of parameters. This represents a challenge in determining the optimal parameters configuration for a certain application. Nevertheless, this technique also enables the control of fiber integrity and morphology by precisely adjusting these parameters. Frequently, it is advantageous to conduct spinning processes at ambient temperature due to the cost-effectiveness compared to operating at very high or low temperatures. All the materials obtained (in the form of nanofibrous mats) and studied for their properties demonstrated potential for **tissue engineering applications** and **wound healing** by bringing **novelty** in this **biomedical field**. Also, the **optimization of parameters** done in this work holds great value for the electrospinning deposition process of different types of materials.
